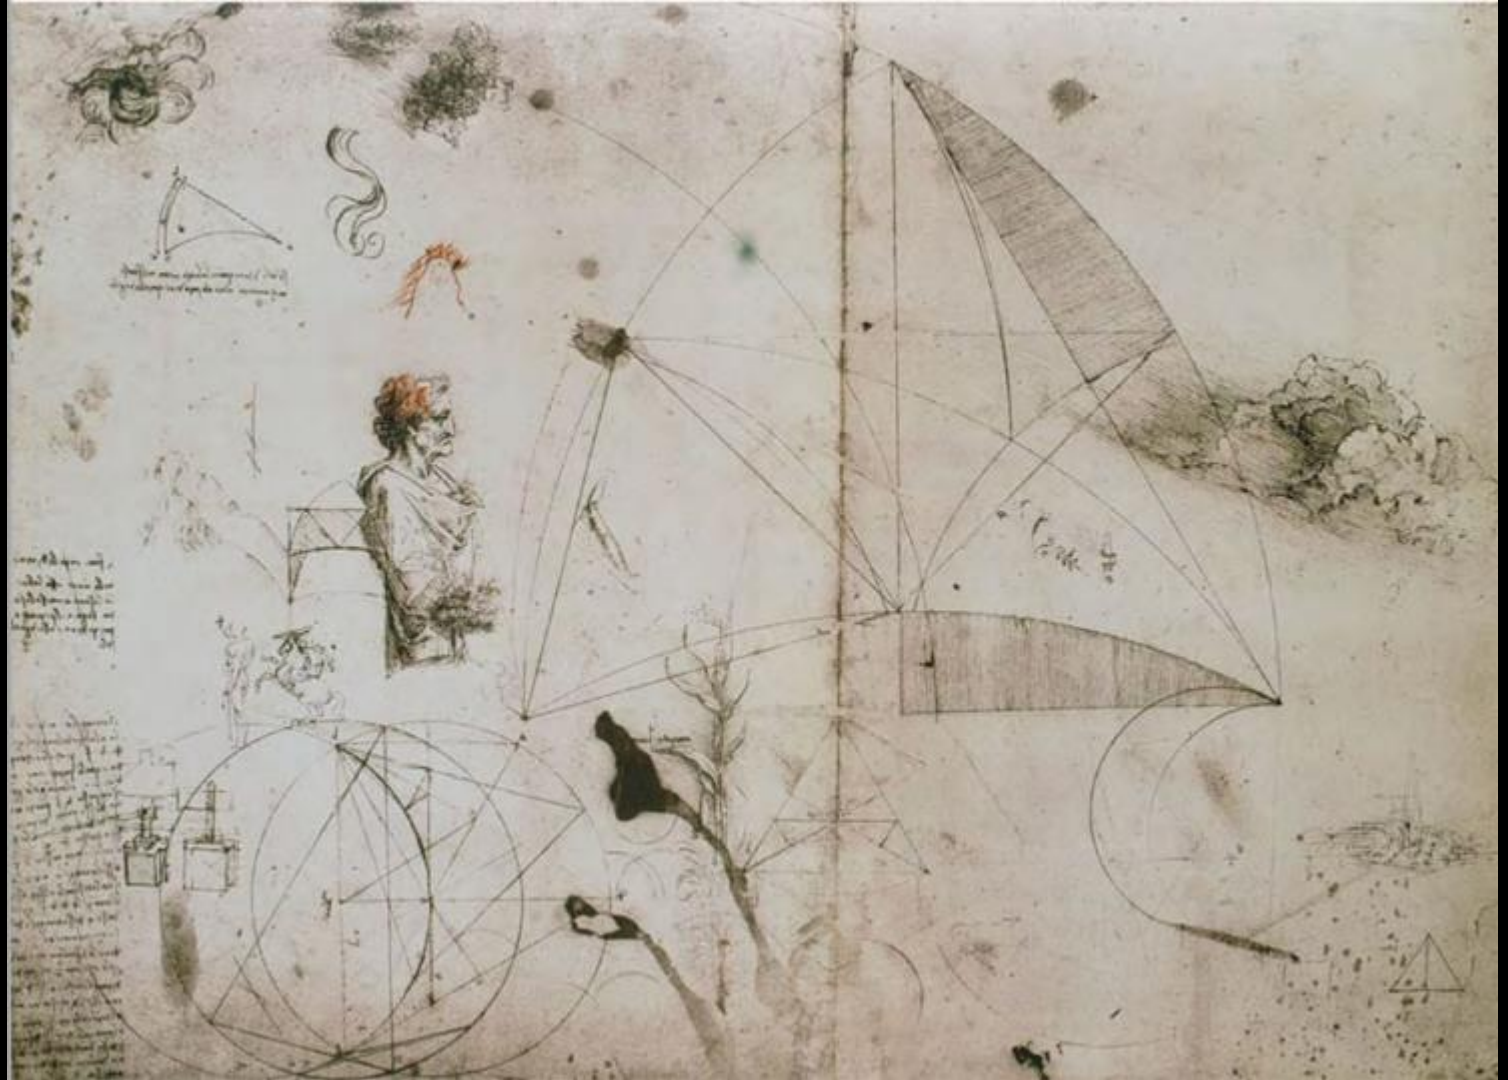
Arch 172: Building Construction 1

Fall 2024

Professor Terri Meyer Boake

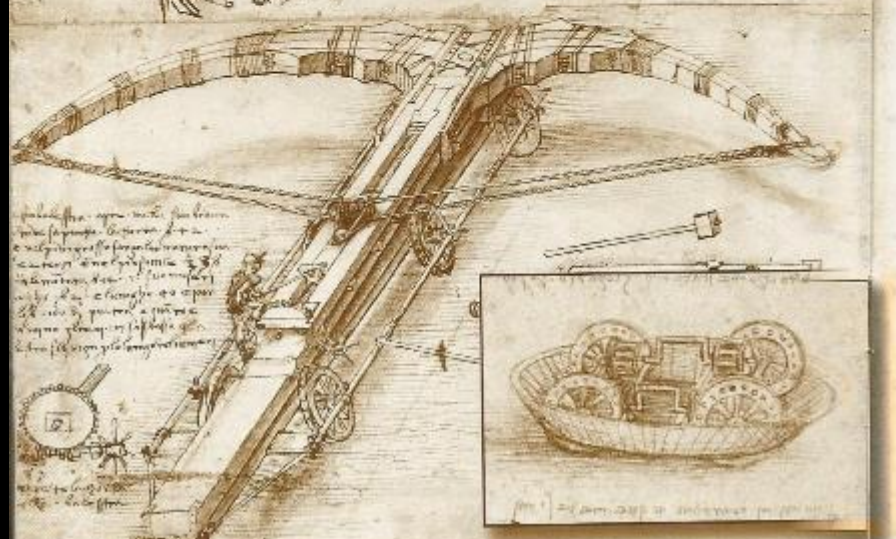
The Sketchbook

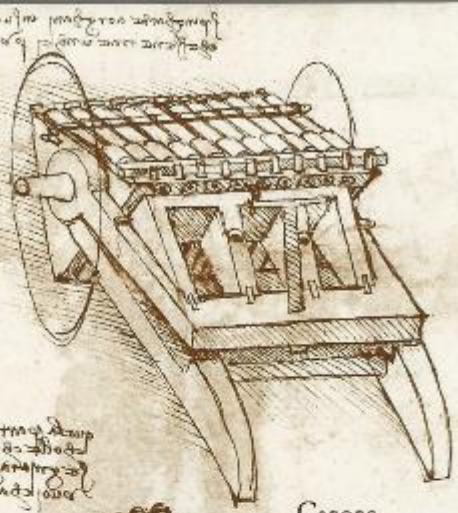


L'ingénieur militaire

Arbalète géante

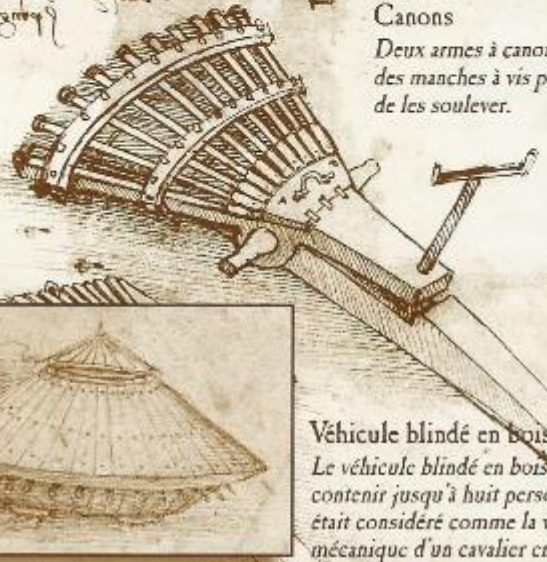
Cette arme effectuait deux actions pour tirer: un coup de marteau relâchait un ressort et un levier redressait l'arbalète.





Canons

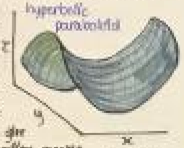
Deux armes à canons avec des manches à vis permettant de les soulever.



Véhicule blindé en bois

Le véhicule blindé en bois pouvait contenir jusqu'à huit personnes et était considéré comme la version mécanique d'un cavalier en armure.

- a hyperbolic paraboloid is a doubly ruled surface shaped like a saddle
- Sometimes an aesthetically satisfying shape has been brought primarily through clarity of structure, as something that can be sufficiently expressive in itself and capable also of giving a recognizable identity to a building & a sense of place to its surrounding.
- TWA Terminal at Kennedy Airport & Utzon's Sydney Opera House have a hyperbolic paraboloid shape. The wind-filled sails had to be constructed not as smooth continuous thin shells but as sets of ribs placed side by side to give a deeply corrugated cross-section capable of resisting the actions inevitably brought into play by the desired sharply pointed edges.



- multistory buildings veer toward convenience of plan and general habitability than toward aesthetics.
- the need to accommodate the increased demands of clients & unpredictable future demands have become a major constraint on the choice of structure.
- Sometime appearance is chosen almost entirely for structural reasons such as water-retaining structures & bridges.

The Development of Structural Forms

- When & where developments take place depend on many things, such local resources, fluctuations in prosperity & the objectives and priorities of those in control.

Chapter 2: Structural Actions

- To make sure a structure does not collapse, we must ensure that the active loads are balanced throughout the structure by the resistances opposed to them, that the loads passed on by the structure as a whole to the foundations are similarly balanced, that there are adequate margins of strength & stiffness under normal circumstances in all structural elements and their interconnections, and that the energy imparted by alternating loads like the wind is safely dissipated.

Loads And THEIR EFFECTS

↳ Active And Reactive Loads

- Among the normal active loads, gravitational self-weight is always present. Since it depends on the structure & the material, it's unchanging & referred to as a dead load.
- Imposed or live loads are those imposed on the structure by its user or its environment. They do change with time & they differ significantly from one another in their effect of how frequently they change, the extent of their dependance on the form & materials of the structure, and the characteristics determined by the manner of its construction. (ex: loads imposed by furniture in a room or people on a bridge)

- within a structure there are also the loads produced by changes in temperature & humidity & even by the setting & hardening of cement when the expansions & contractions to which these tend to give rise are restrained.
- Balancing the net effects of most of these active loads at the point where the structure is supported are the normal reactive ones. The also depend on the precise manner of construction.
- Examples of reactive loads include internal air pressure

↳ Associated Movements & Deformations

- All types of load tend to produce movement in in the direction in which they act.
- The term 'stiffness' denotes the resistance that is ~~[illegible]~~ developed by a given deformation and 'strength' the maximum resistance that can be developed. Both can have different values for the same element.

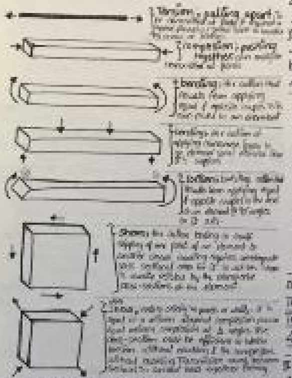
↳ Dynamic & Static Loads

- Static loads change slowly enough to allow the resistances that are developed by deformation to keep pace with them.
- Rapid changes of loads involve significant acceleration which cause inertial resistance to the mass being accelerated. Sometimes balance is overshot.
- the amount of time a dynamic load takes to reach its peak is proportional or less than the natural period.
- Instantaneously applied loads have twice the effect of a load of the same magnitude applied slowly
- rhythmically repeated or periodic loads most damaging effects if their repetition attune in with natural vibration. A state of resonance is then encountered, with each successive application of the load reinforcing the effects of the previous application.
- Static loads are the most important ones for most cultures.
- Dynamic & periodic loads of comparable magnitude are usually of special & infrequent occurrence.
- The commonest dynamic load is wind. The external form & orientation of the structure should equalize the pressure on different faces.
- noticeable dynamic effects are usually confined to structures with long natural periods of vibrations. (ex: tall slender buildings, chimney stacks...)
The effects can be greatly magnified by [illegible] of the cross-section to one that leads to a regular formation & shedding of vortices roughly in step with the natural vibrations.
- dynamic loads due to earthquakes are less common; they are inertial loads acting on all parts of a structure when the ground as a result of very rapid displacements of its foundation. They depend on the mass of the structure & vibrations of the whole structure & its elements, on whether they respond by bending, rocking, and ability to dissipate energy.

Internal Actions

↳ Tension, compression, bending, torsion, & shear

- A single force is represented by a straight arrow and a pair of equal & opposite parallel forces, that tend to cause rotation, by a curved arrow.



- Each type of action may also occur at joints between elements.
- Elements with large cross-section areas are required to resist bending or torsion
- Appreciable cross-section areas are required to resist compression because any departure from collinearity in the load will result in bending that will increase the vulnerability & may lead to buckling.
- Non-static tensile load tends to realign the element with the load so that smaller cross-section areas are adequate.
- ~~[illegible]~~ Transmission of bending requires a joint that resist compression, tension, & shear (& torsion) [illegible]

↳ Actions of Human Frame

- Skeleton resists compression & a limited amount of bending. Tension is taken by the ligaments & muscles.
- Rotation of bones depend on the joints between them. Thus, they are capable of transmitting compression & some tension and shear & limited amounts of bending and torsion when no further rotation is allowed.
- bending & twisting are resisted by the whole frame.
- To maintain static balance, the body often alters the stance or adjusts the magnitude of the internal tension & compression.

↳ Actions of The Built Structure

- All subsequent behaviour depends on external circumstances.
- Humans can't easily tell how all the structure respond.

Structural Requirements

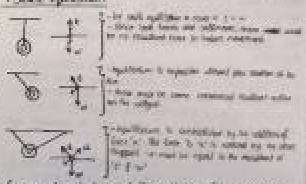
↳ The Basic Geometric Requirement

- In order to form a stable system & not just a loose assemblage, the elements must be ~~[illegible]~~ joined in a 3-D space inhabited by the structure & in the face of all likely loading.

↳ The Complementary Needs for Adequate Strength & Stiffness

- If the geometric requirement is satisfied, the individual elements & joints should have the requisite strength & stiffness.
- In complex structures the nature of the elements is determined by exploring the balance of the forces @ work - static equilibrium.

↳ Static Equilibrium



- For a system to be in static equilibrium, it must have a zero linear resultant in every direction, & have no resultant moment.

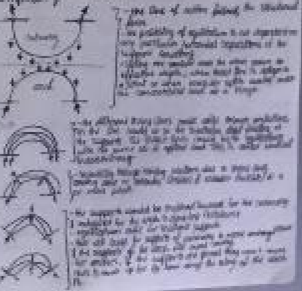
The Equilibrium of Some Structural Elements Acting in Simple Tension or Compression

↳ The Catenary & The Arch

- Both are unstable structures. The arch would fall to the ground if loaded & the catenary would merely change its shape to the position necessary to self-equilibrating. [illegible]

- Since [illegible]

- The [illegible] internal forces will be [illegible] in the catenary or the arch, [illegible] tension or compression.



HISTORY OF WOOD

Wood is pretty good in tension and bending; resilient under repeated loads
↳ trees are continually flexing & they hold their strength

Wood Construction Structural Types:

- heavy bearing wall (solid)
- post and beam
- light framing → more so residential construction (unique to wood construction)

Advantages of wood:

- natural material
- renewable (if carefully managed)
- sequesters carbon → helps with greenhouse gases
- easily worked with hand tools on site

Disadvantages of wood:

- burns - rots
- food for termites and carpenter ants
- not available everywhere
- height limited (related to burning, maximum in Canada is 6 storeys)
- natural insulator so cannot store heat
  ↳ materials like stone are thermomass materials meaning they absorb heat

History:

- 1st timber house in Britain (mesolithic period)
- Neolithic long house during 4000 B.C.E.
- tools made of wood, then adding metal (iron/copper); metal saw
- Iron age: wooden molds used to shape clay, adobe etc.
- increase in wood precision / metal / steel improved tools), Egypt had to gather every bit of wood to build the pyramids
- at this time, woodlands were cleared dramatically (50%)
- invented timber crane
- Middle Ages: carpenters were sought out
  - water mills were invented (could cut/manufacture materials)
  - Westminster hall, temples in China
- 21st Century: in N.A. wood extremely plentiful

Historic Wood Architecture of Japan

- cedar wood; distinct to Japan (smooth and fine-grain texture)
- oldest known temple, Pagoda, 1800, made of cedar

THE INTRINSIC CONNECTION BETWEEN ARCHITECTURAL DESIGN AND STRUCTURAL MATERIALITY

INTRO LECTURE

THE PYRAMIDS OF GIZA
2560 BC
- the ability of a material to withstand force is its most important attribute
- made of stone (compression material)

THE PARTHENON, GREECE
- also made of stone
- [illegible]

THE ROMAN COLOSSEUM
ROME, ITALY
80 AD
- the Romans invented the arch

THE PANTHEON
ROME, ITALY
126 AD
- [illegible]

SANTA MARIA DEL FIORE
FLORENCE, ITALY
1436

[illegible]
- [illegible]

Stone: From Technique to Technology

- early on history, 'trial and error' was the way to build

Aesthetics

- a branch of philosophy that explores the notion of art, beauty, and taste, with creation and appreciation of beauty

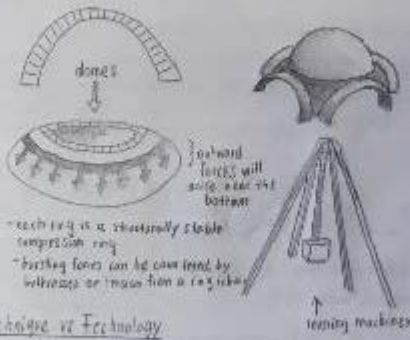
Stone:

- natural material
+ great for compression
- some stones are better for construction e.g. sandstone is very brittle/cracks easily
- stone gets destroyed by pyrenes
- water imparts materials, mass and tubers can also deteriorate

Forces

- tension i.e. stretching
- compression i.e. crushing
- moment/torque i.e. bending

Using the ARCH to Span



Technique vs Technology

- trial and error vs. mathematics and physics

Stonehenge

3000 B.C.E, Wiltshire, England

- historians not sure how it was built
- sundials, clocks, advanced stone placement

Law of Hammurabi

1750 B.C.E.

- basically, if a builder built a house and that building fell and killed someone, the builder would be put to death

Ancient Stone Techniques

Egypt: used ramps to move heavy objects (stones)

Stepped Pyramid of Djoser at Saqqara (27th Century B.C.E.)

- surroundings currently in bad repair
- rough stone to restore because sandstone is eroding

Pyramids of Giza

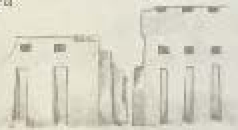
Khufu/Cheops, Khafre/(Chephren and Menkaure)
2580 B.C.E.

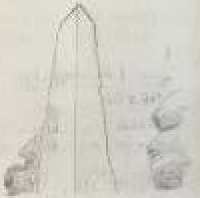
- Tomb sits at the bottom of the pyramid
- grave robbers stole a lot of riches from vaults
- the finished stone were away: sold them leaving very rough and coarse

Temple of Karnak

Thebes, Egypt 2050 B.C.E.

- temple that was created while the pharaoh was alive : not a tomb
- dedicated to the deity that the pharaoh worshipped
- goal was to impress
- many columns - spaced as far as stone can span
- hypostyle hall : where the roof is supported by a vertical row of columns

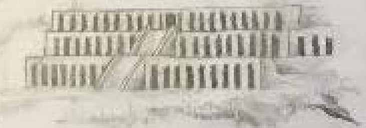




Mortuary Temple of Hatshepsut

Valley of the Queens, Egypt 1478 B.C.E

- Simpler style
- covered completely using with nicer, more expensive stone (facade)
- hieroglyphs were sometimes painted
- very colourful and painted, paint has worn away over the many years



Abu Simbel, Pharaoh Ramesses II

Aswan Egypt, 13th Century B.C.E - relocated in 1968

- two temples cut into the cliff
- interior was a modified hypostyle hall - less columns
- more interior space
- columns were statues, painted very colourfully

Tomb of Ramesses VI

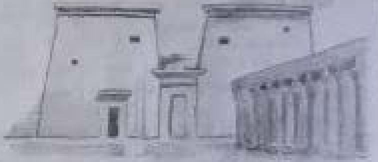
Valley of the Kings 1145 B.C.E

- intentionally hidden in desert

The Temple of Isis at Philae

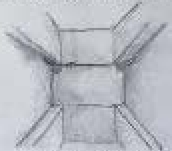
Aswan, Egypt 380 B.C.E

- many carved capitals, human figures & nature (lotus leaves)
- each capital is inconsistent
- materials (stone) seriously restricts the ability for them to span
- they had no wood because no trees



The Temple of Horus at Edfu

Edfu, Egypt, Ptolemaic Kingdom 237 B.C.E



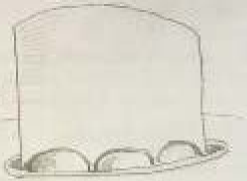
- colonnade (row of columns) lots of symmetry
- all interior spaces were for ceremonies etc
- corner capitals similar to the temple at Philae
- spacing between the columns are small
- stone planks on top to make the ceiling
- space is dense, heavy, and full of columns
- columns surround a courtyard
- contains hypostyle hall

MIT Chapel

Cambridge, Massachusetts (1955)

Eero Saarinen

- cylinder
- modern movement, very simple
- little arches along bottom
- moat along bottom that reflects light into the chapel
- solid masonry walls
- skylight over raised pedestal, "sparkles" [illegible]
- interior brick design pattern is different from exterior



MIT Chapel

Rothko Chapel

Houston, Texas (1971)

Philip Johnson

- extremely simple and reflective of modern movement
- [illegible] [illegible]; flat roof made [illegible]

Phillips Exeter Library

Phillips Exeter Academy Library

Exeter, New Hampshire (1972)

Louis I. Kahn

- modern, regular [illegible] ("formalist") symmetrical
- "bench" in the design
- exterior is brick, interior [illegible] concrete
- large open space + galleries

Palmer Museum of Art

Penn State University, State College, Pennsylvania (1990)

Charles W. Moore

- "post modern" ← [illegible]
- revival of classical architecture [illegible]
- arches, [illegible], [illegible] ([illegible] [illegible] and [illegible])
- symmetry and [illegible]
- [illegible] with [illegible] masonry (small brick [illegible] are adaptable to different shapes in structures)

Brown College

Rice University, Houston, Texas (2002)

Michael Graves

- masonry, [illegible] [illegible]
- decorative brick laying
- flat [illegible], [illegible] [illegible] [illegible] [illegible] [illegible] [illegible]
- wooden arches to support ceiling
  - → [illegible] building [illegible]; same style with brick

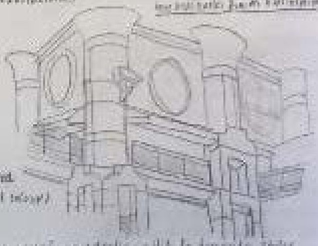
Herring Hall

Rice University, Houston, Texas (1984)

Cesar Pelli, Architect

"post modern"

- [illegible] made of stone + bricks (specially manufactured)
- [illegible] colors, brick patterns
- [illegible]
- [illegible] + [illegible] [illegible]
- [illegible] [illegible] [illegible]



Anne and Charles Duncan Hall

Rice University, Houston, Texas (1996)

John Outram Associates

- arches, capitals
- [illegible] brick detailing, some are glazed
- colorful interior (teal, [illegible] dominant [illegible])
- [illegible] [illegible] ceiling

From a stylistic perspective, Rice has insisted on eclectic attitude towards styles and [illegible]

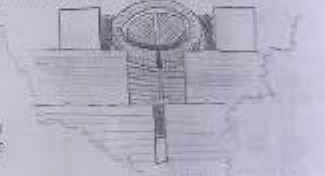
Brick can be made as large precast panels and hung from the building to make a [illegible] [illegible] [illegible] [illegible] at height in [illegible] weather

Museum of Modern Art

San Francisco, California (1995)

Mario Botta

- [illegible], square [illegible], [illegible]
- "[illegible]"
- fairly symmetrical
- [illegible] [illegible], [illegible] [illegible], brick panels
- red brick [illegible] [illegible] [illegible] brick panels



Museum of Modern Art - front

Millennium Science Complex

Penn State University, State College, Pennsylvania (2011)

Rafael Viñoly Architects

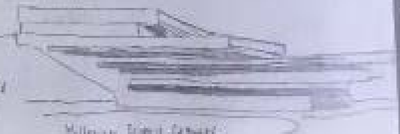
- massive cantilevers
- brick panels that were pre-fabricated - construction [illegible] easier
- special [illegible] in the underside

Dr Chau Chak Wing Building

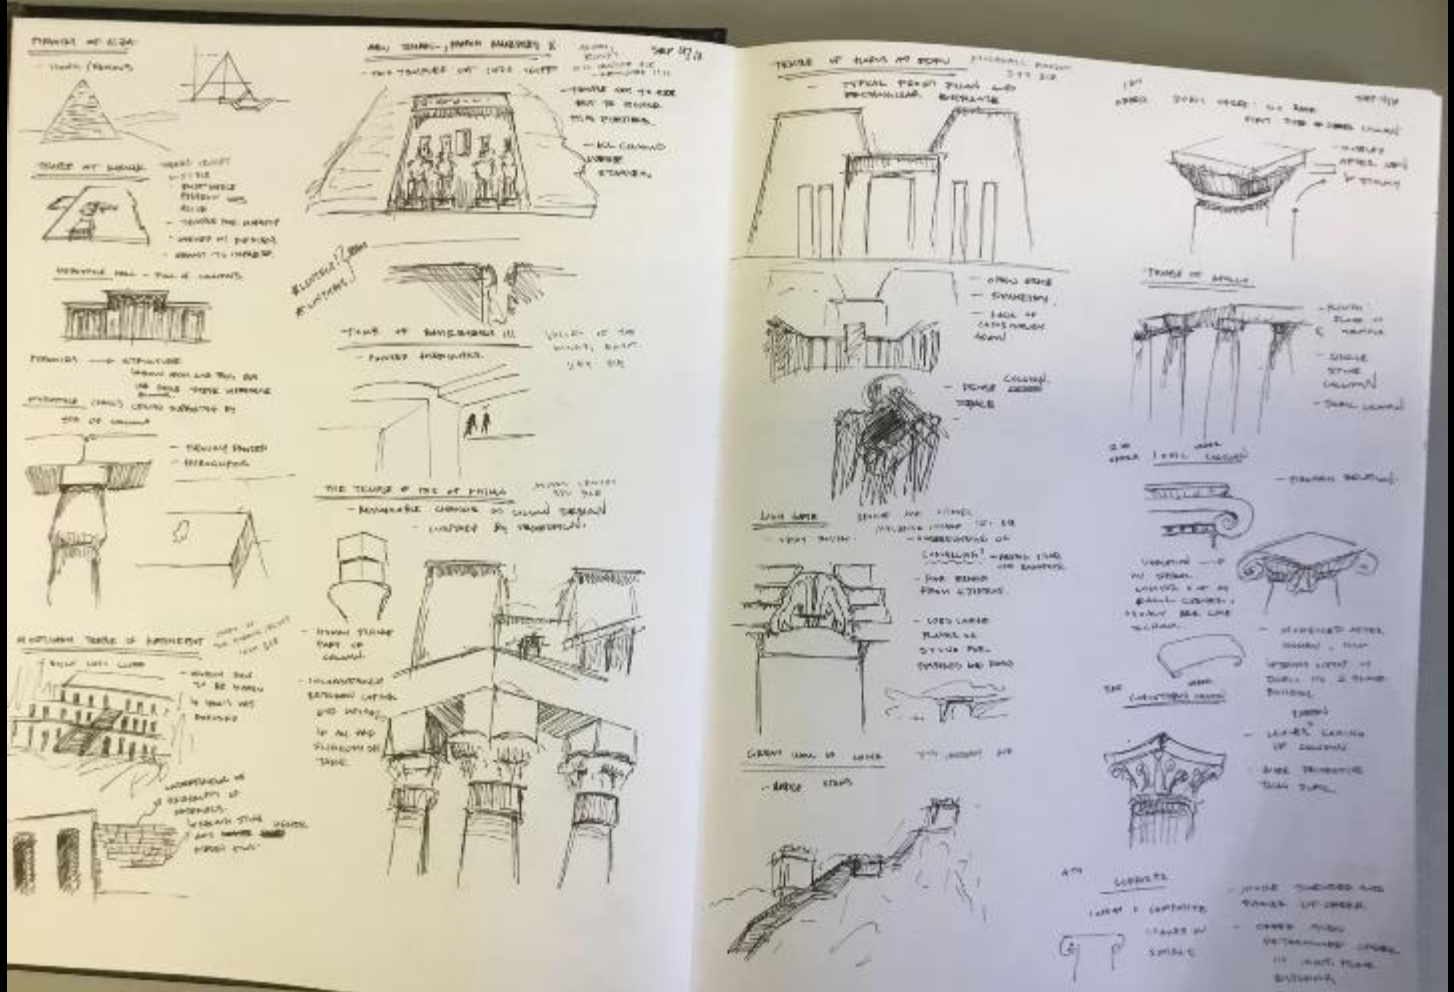
Sydney, Australia (2015)

Frank Gehry

- [illegible]; [illegible] [illegible] [illegible]
- custom pre-fabricated brick [illegible]



Millennium Science Complex



[THE RENAISSANCE]

- [illegible]
  - mosaic painted as frescoes
- [illegible]
  - multiple columns + designs
  - inspired by vegetation
  - size limited by ability of material to span
  - all temples had a different [illegible] individuality?
- [illegible] at Karnak, 1530 BCE
  - formalized open space
  - surrounded by columns (peristyle)
  - symmetry of space
  - allows light to enter
  - space is dense, no. of columns
- [illegible] 1350 BCE
  - limestone
  - smoother lines
  - fortification (thick)
  - corbeling (support structure like an arch or balcony)
- [illegible] 7th century BCE
  - steel + stone
- Order of columns → DORIC order
  - columns → not different visibly in Egypt
  - similar inside temple
  - reflecting all human body
- [illegible]
  - columns carved in one piece
  - Greeks + added mathematics into their art
- [illegible] circa 550 BCE
- [illegible] 500 BCE
  - different capitals
  - colonnade around perimeter
- [illegible] Greece
  - columns, carved as women to hold up porch
- [illegible] (Greece)
  - huge columns, mainly
- [illegible] (Italy)
  - typical temple architecture
- [illegible] 497 BCE
  - style of architecture more refined
- The CLASSICAL STYLE → used ROUND ARCHES

- [illegible]
  - promenade around arches
- [illegible] Italy
  - walls plastered over
  - originally coloured

Building Work

THE OUTDOOR ENVIRONMENT

The Earth and the Sun

- Sun is an important factor in the lives of people and buildings
  - warms body + buildings by direct radiation or warming the surroundings
  - illuminates outdoors, disinfects surfaces, produces vitamin D
- Sun is both a giver of life + destroyer
  - disintegrates materials, burns, promotes skin cancer
- sunlight includes electromagnetic radiation
- Earth is closest to the sun in winter, so the orbital eccentricity helps to slightly moderate seasons
- seasons created by tilt between axis of Earth's rotation + a perpendicular to the plane of its orbit

The Equinoxes

- March and September 21
  - vernal equinox
  - autumnal equinox
- North and South pole are equidistant from the sun
- Sun rises and sets exactly [illegible] of extreme poles – sun travels along horizon for 24 hrs

The Annual Cycle

- over the course of a year, every point on the globe is exposed to direct sunlight exactly half the time
- @ the poles, [illegible] portion of sunlight comes in one continuous 6-month period
- @ the equator, each day of the year is evenly divided between daylight and darkness
- @ intermediate latitudes, longer summer days compensate for shorter ones in winter

The Summer Solstice

- occurs when the sun rays are at right angles at an orbital position (normally around June 21)
- The sun is seen for a longer period of time on this day than other days
- warmest season occurs later since land + water hold considerable solar heat during warmer days
- later, Earth gives back the stored energy to cooler air (moderating the effect)
- winter solstice – opposite (Dec 21)
  - fewest hours of sunlight

Effects of Solar Radiation on Earth

- length of day
- angle of incidence of sunlight on the ground at each time of day
- amount of atmospheric [illegible] by the radiation at each time of day

The Sketches

Architects do sketches all through the design process.

Most are "quick and dirty"

Unless you become super famous, nobody will ever want to frame them and they won't get given to your grandmother for her birthday.

Architectural sketches are mostly lines, no shading

Hatch is used sparingly to create depth.

The lines are all hand drawn, pretty straight, but with a bit of attitude

Check out my Pinterest board for some good examples

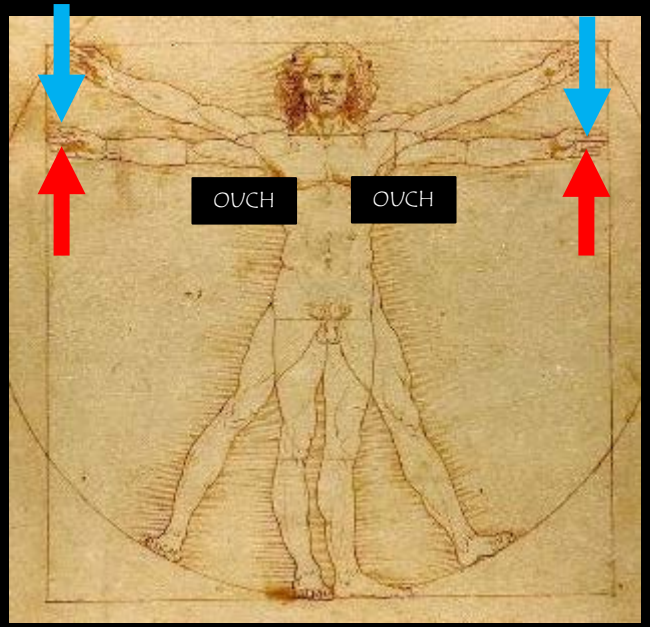
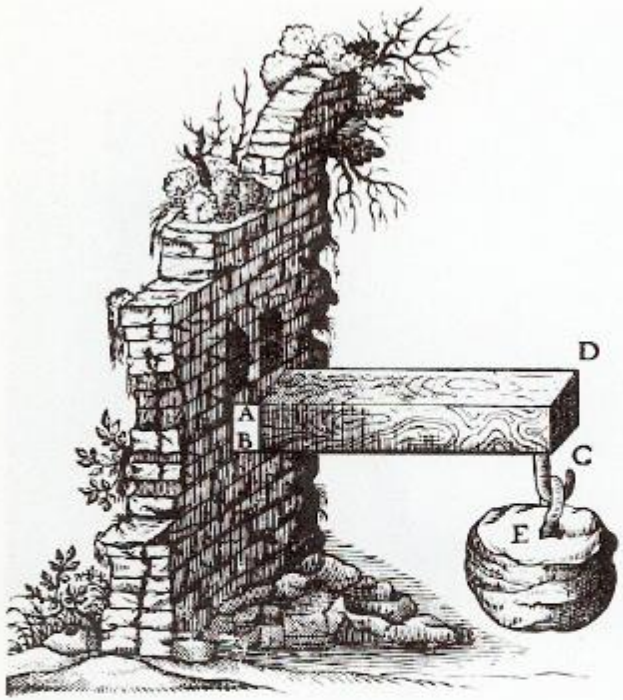
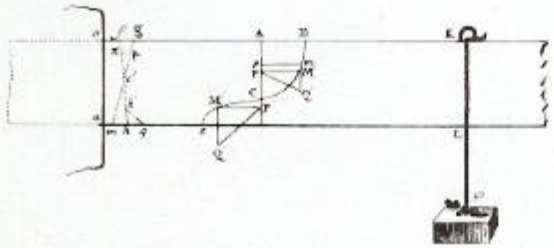
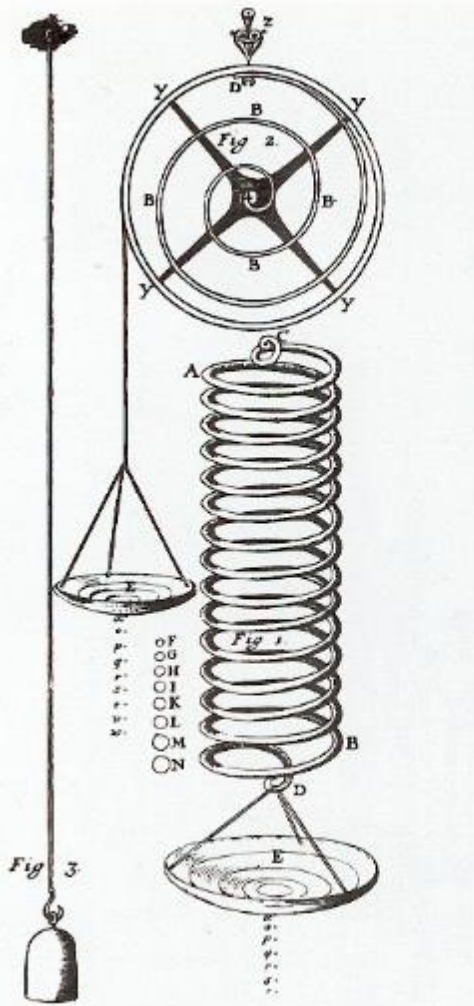
BENDING





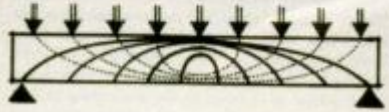




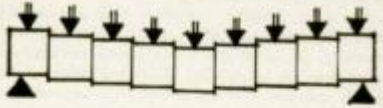
16.9 (*far left*) Studies of the behaviour of a cantilever beam by Galileo (top) and Coulomb (bottom). Galileo assumed that rotation would occur around the bottom edge at B. Coulomb more correctly assumed that the internal stresses over the depth of the cross-section would vary continuously from compression at the bottom to tension at the top, and that, in addition to these stresses acting longitudinally, there would be vertical shear stresses.

16.10 (*left*) Studies of elasticity by Hooke.

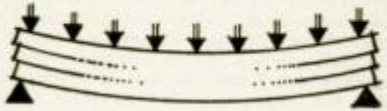
Light interference patterns showing stress in a plastic model beam under polarized light



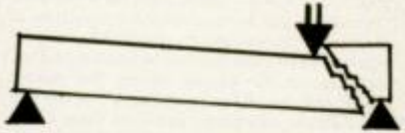
Lines of pressure and tension in a beam



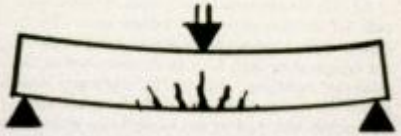
Vertical shear in a beam



Horizontal shear in a beam

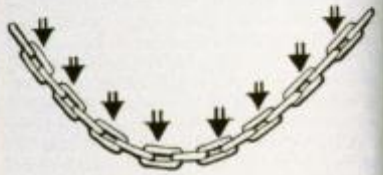


Shear failure near support

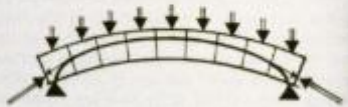


Bending failure over two supports

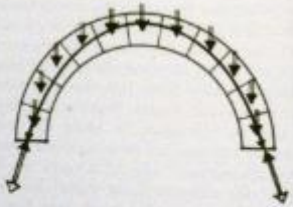
Beam bending and opening of lower surface in tension



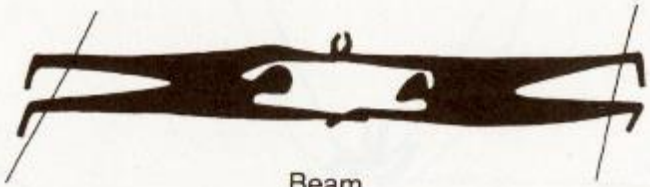
Tensile structure alone: a chain suspended from two supports conforming to line of tension in a catenary curve



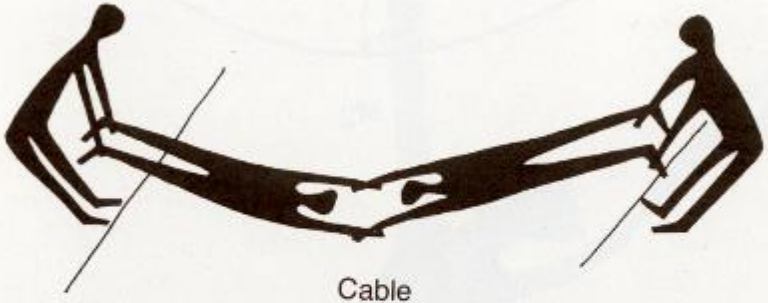
Compression structure alone: a masonry arch wedged into position along line of compression in a reversed catenary curve



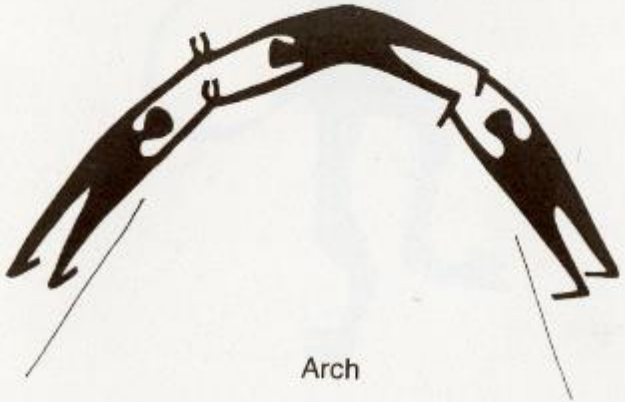
In the semicircular masonry arch the line of pressure does not conform to the shape of the arch and therefore the crown tends to fall while the sides buckle out.



Beam

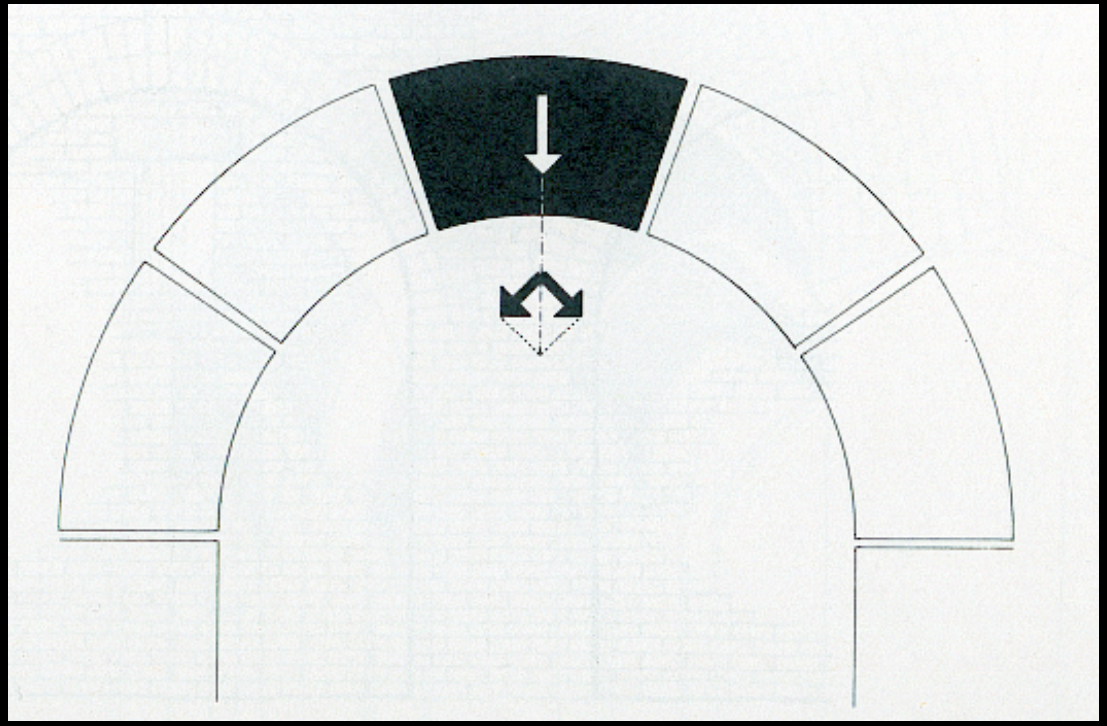


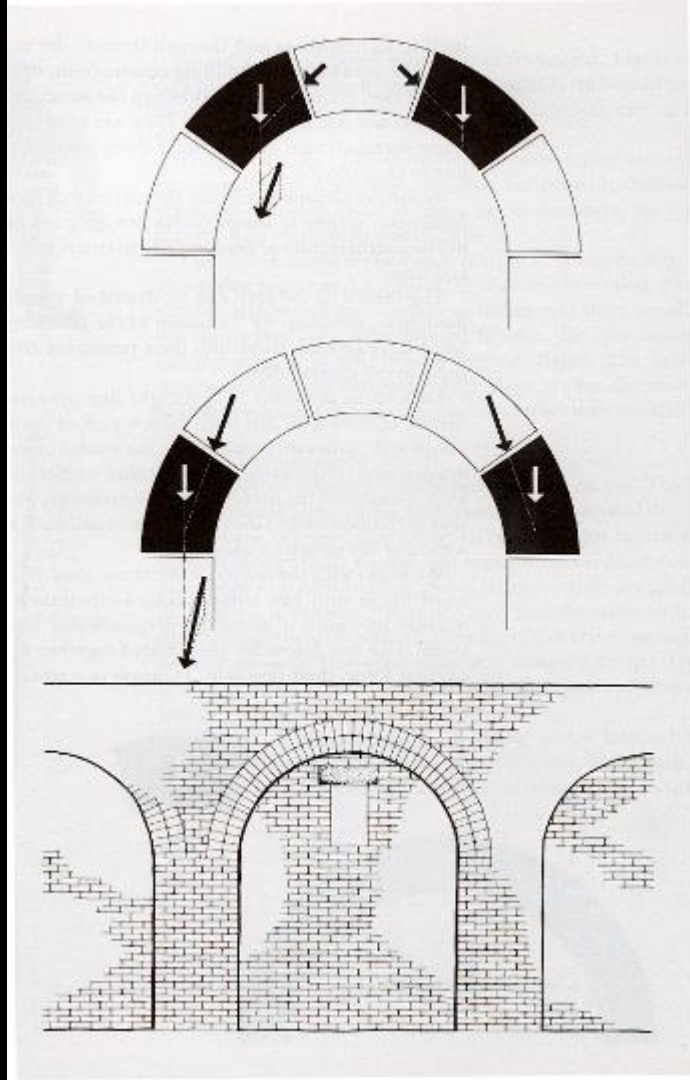
Cable



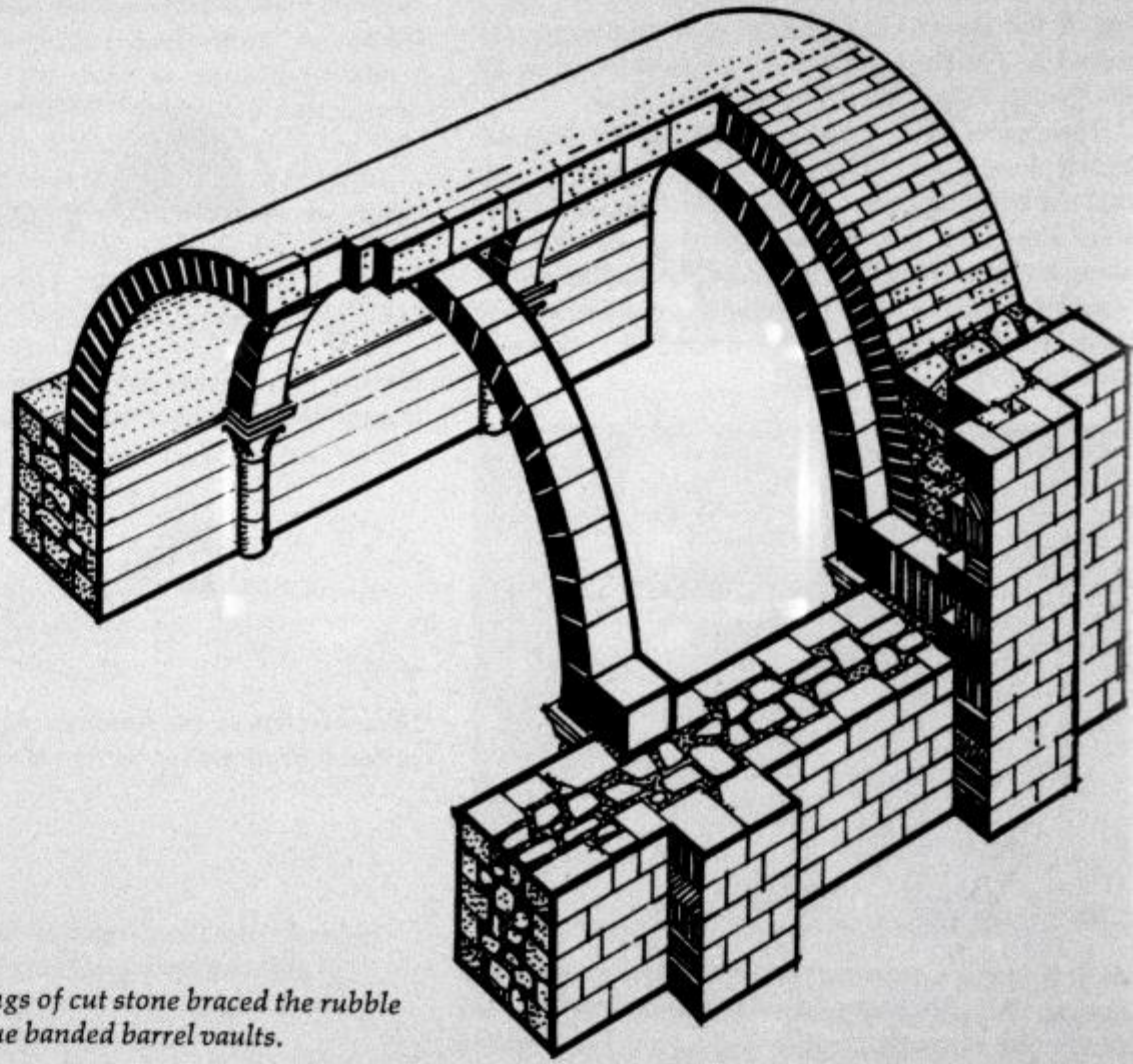
Arch

Using the arch to SPAN

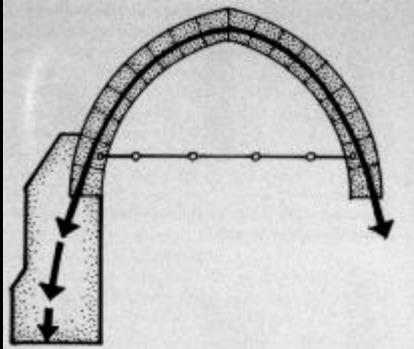




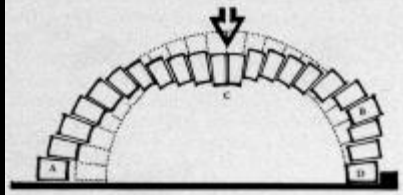
A BARREL VAULT is essentially a row of semi circular arches sitting so tightly in a row as to make a continuous, linear arched space (room)



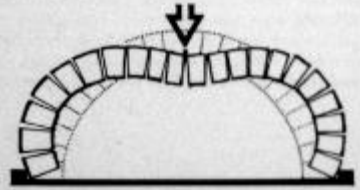
Transverse arch rings of cut stone braced the rubble shell in Romanesque banded barrel vaults.



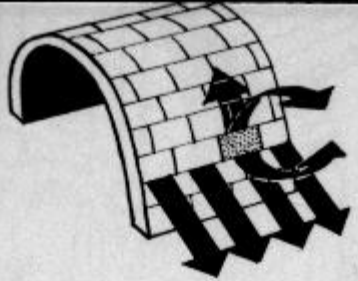
Though the pointed Gothic arch better fits the ideal line of pressure, if too acutely pointed the crown tends to rise while the sides fall inwards. (Similar to saddle failure in pointed corbel vaults)



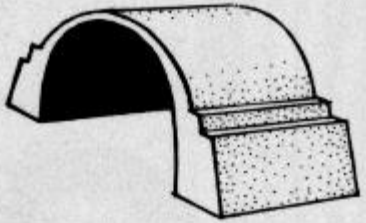
In a semicircular arch where the stones can slide the crown C will fall while the sides B are pressed out above a secure springing D or at the springing itself A.



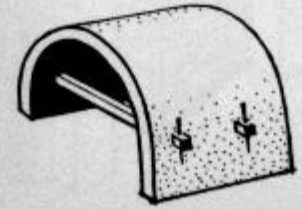
More normal is the rotational deflection of the stones during failure.



A barrel vault exerted a continuous thrust along its sides.



Usually the thrusts were dissipated in the heavy mass of the haunching and the supporting walls.

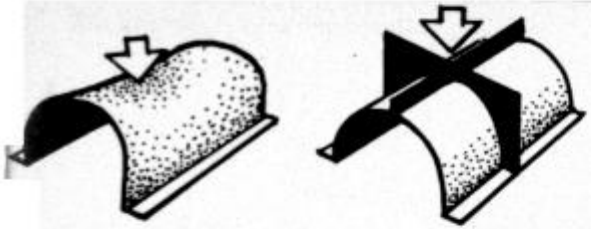


In rare instances, the masons used timber ties to restrain the thrusts of the barrel vault.

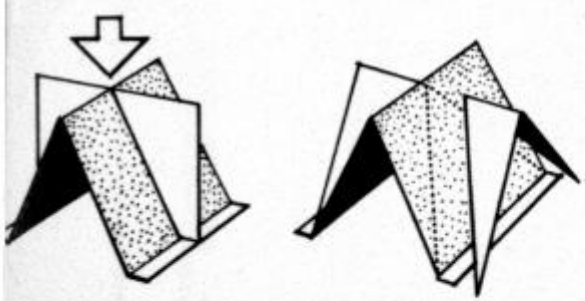
BUTTRESS

A projecting support of stone or brick against a wall

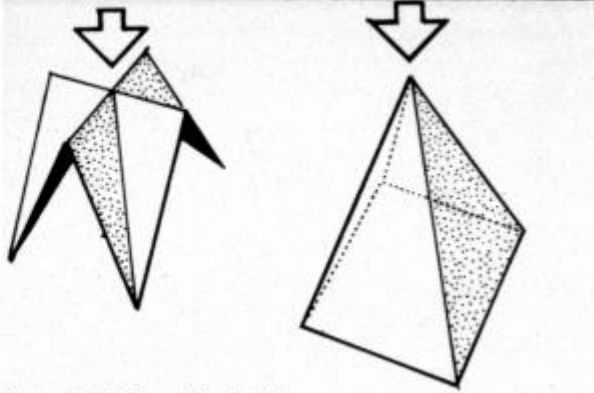
A GROIN VAULT or groined vault (also sometimes known as a double barrel vault or cross vault) is produced by the intersection at right angles of two barrel vaults.
The word "groin" refers to the edge between the intersecting vaults.
The arches may be round (Roman) or pointed (Gothic).



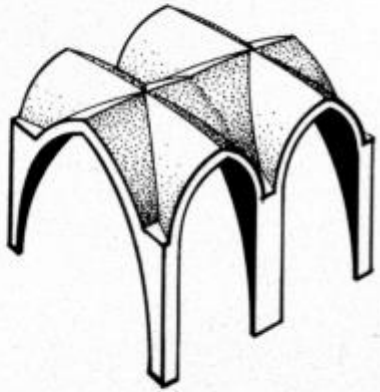
hin cylindrical barrel vaults fail when the crown alls, pushing out the sides. Thin stiffening plates an reduce this flexure.



olding along the crown can replace the longitudinal tiffener. Folded ridges set transversely can brace he sides.

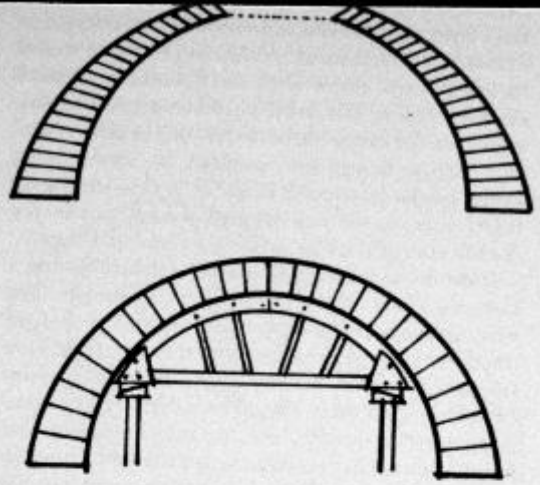


A pyramidal roof is rigid but requires support below the sides. The cross-ridged roof can rest on four isolated supports, channeling loads down the folded groins.

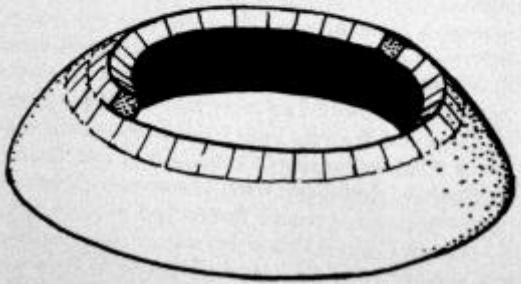


In the pointed Gothic cross vault the panels of aulting were curved to wedge into position

to make a DOME
you take an arch,
and rotate it 360degrees to make a circular space



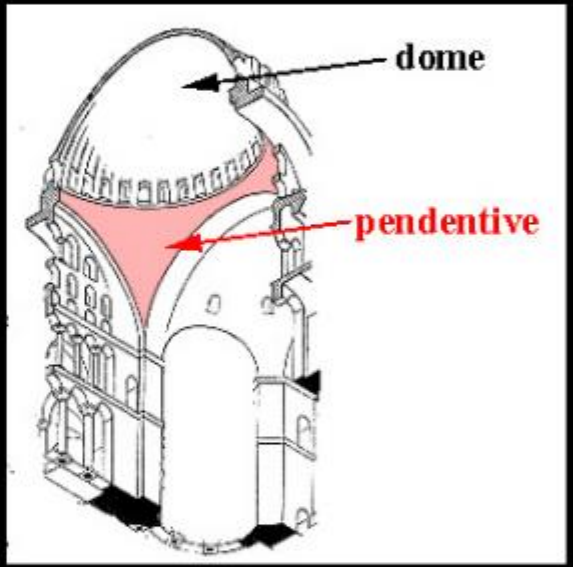
The first domes were developed from beehive corbelled domes by slightly canting the courses. Later domes with steeply pitched radiating joints required centering.

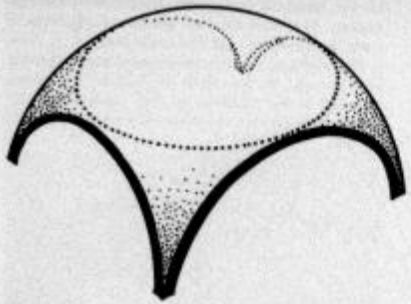


Each ring of masonry in a dome is a structurally stable compression ring.

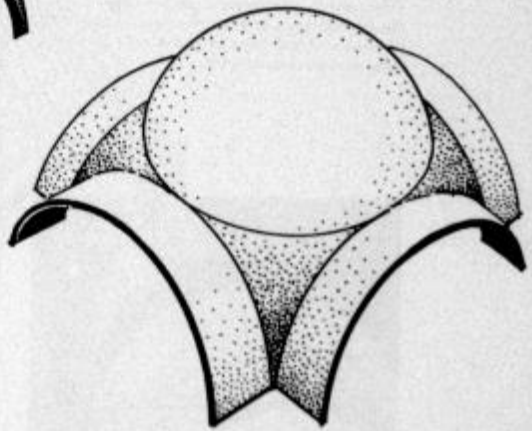
This is what it feels like to be a dome.

a PENDENTIVE is a constructive device
permitting the placing of a
circular dome over a square room
or of an elliptical dome over a rectangular room.





In domes on pendentives the mason could rely on the stiffness of doubly curved surfaces.



In Gothic cross vaults the folds at the groins acted as stiffening ribs bracing the entire fabric.

Law Code of Hammurabai
1750 BCE

If a builder build a house for a man and do not
make its construction firm,
and the house which he has built collapse
and cause the death of the owner of the house,
that builder shall be put to death.
If it cause the death of a son of the owner of the house,
they shall put to death a son of that builder.

CHAPTER I

THE EDUCATION OF THE ARCHITECT

1. The architect should be equipped with knowledge of many branches of study and varied kinds of learning, for it is by his judgement that all work done by the other arts is put to test. This knowledge is the child of practice and theory. Practice is the continuous and regular exercise of employment where manual work is done with any necessary material according to the design of a drawing. Theory, on the other hand, is the ability to demonstrate and explain the productions of dexterity on the principles of proportion.

2. It follows, therefore, that architects who have aimed at acquiring manual skill without scholarship have never been able to reach a position of authority to correspond to their pains, while those who relied only upon theories and scholarship were obviously hunting the shadow, not the substance. But those who have a thorough knowledge of both, like men armed at all points, have the sooner attained their object and carried authority with them.

3. In all matters, but particularly in architecture, there are these two points: — the thing signified, and that which gives it its significance. That which is signified is the subject of which we may be speaking; and that which gives significance is a demonstration on scientific principles. It appears, then, that one who professes himself an architect should be well versed in both directions. He ought, therefore, to be both naturally gifted and amenable to instruction. Neither natural ability without instruction nor instruction without natural ability can make the perfect artist. Let him be educated, skilful with the pencil, instructed in geometry, know much history, have followed the philosophers with attention, understand music, have some knowledge of medi-

THE ENTASIS OF COLUMNS

1. The entasis as given by Fra Giocondo in the edition of 1511.
2. The entasis from the temple of Mars Ultor in Rome compared with Vignola's rule for entasis.

2. The pycnostyle is a temple in an intercolumniation of which the thickness of a column and a half can be inserted: for example, the temple of the Divine Caesar, that of Venus in Caesar's forum, and others constructed like them. The systyle is a temple in which
